Readings

- The Atlas for the Aspiring Network Scientist
 - Chapter 40
 - <https://www.networkatlas.eu/>
- The node vector distance problem in complex networks, ACM Computing Surveys (CSUR) 53 (6), 1-27

NVD: What?

- A graph G

NVD: What?

- A graph G
- Two vectors v_1 and v_2
 - One value per node
- How far is v_1 from v_2 ?

NVD: Why?

(a) Face #1

(b) Face #2

NVD: Why?

NVD: Why?

(a) Korea 1962

(b) Korea 2013

(c) Egypt 1962

(d) Egypt 2013

NVD: Why?

Re-Cap on Distances

- Euclidean “straight line”

$$\sqrt{(p-q)^T I (p-q)}$$

- Mahalanobis “bendy” space

$$\sqrt{(p-q)^T \text{cov}(p,q)^{-1} (p-q)}$$

Euclidean vs Network

$(1, 0, 0)$

$(0, 1, 0)$

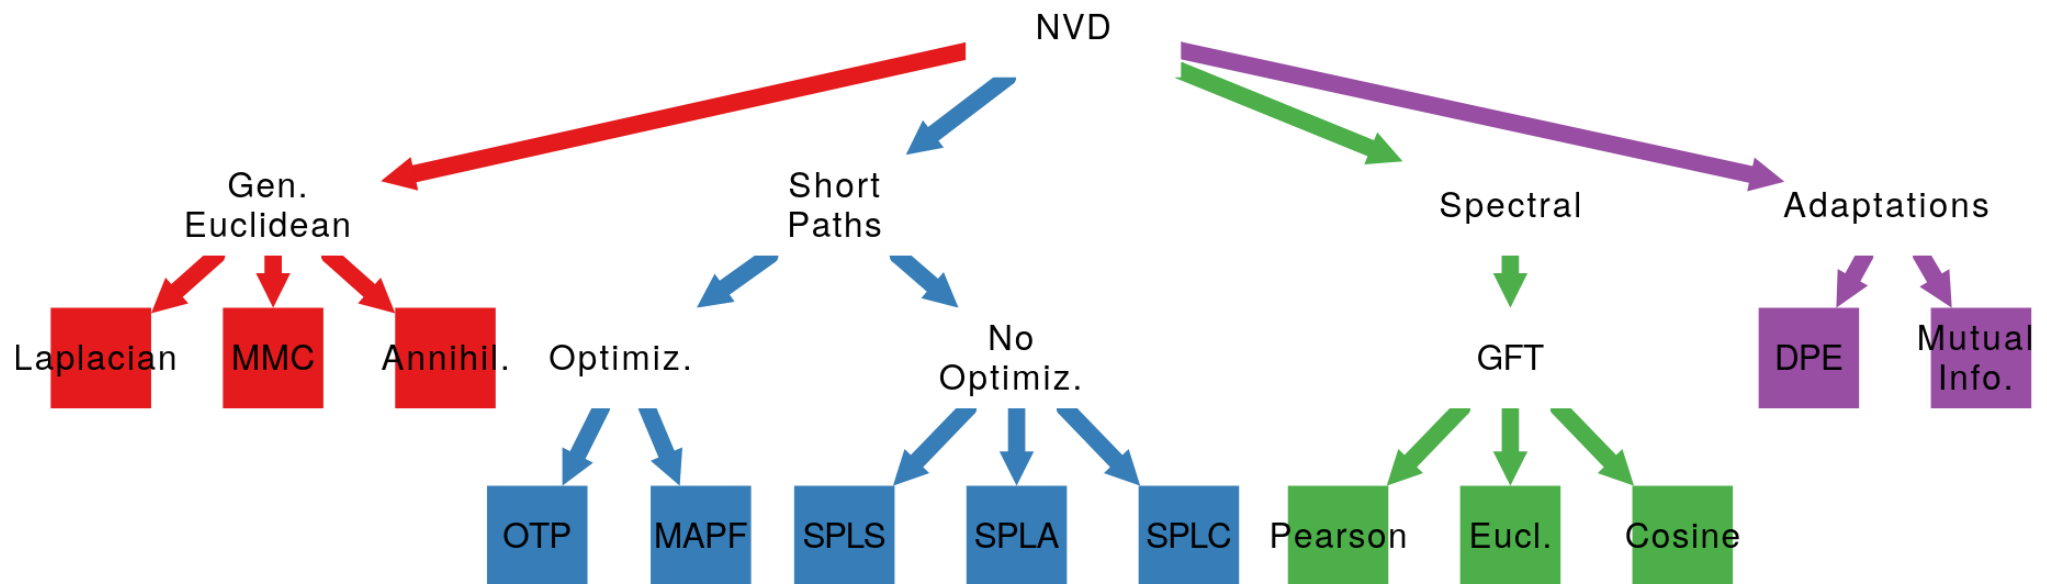

$(0, 0, 1)$

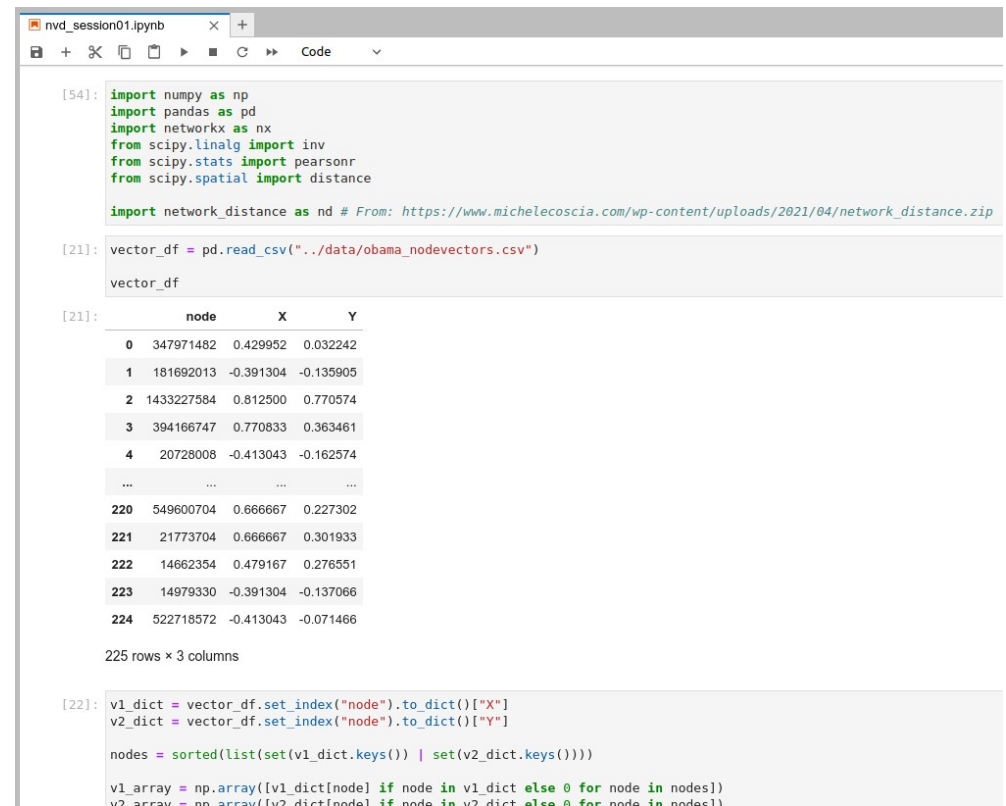

Same Euclidean distances, different network distances
The network “bends” the space, like in Mahalanobis

Current Methods

Tutorial Part #1

- Objectives:
 - Refresher on vector distances
 - Understand I/O of library
 - Set up the data

```
[54]: import numpy as np
import pandas as pd
import networkx as nx
from scipy.linalg import inv
from scipy.stats import pearsonr
from scipy.spatial import distance

import network_distance as nd # From: https://www.michelecoscia.com/wp-content/uploads/2021/04/network_distance.zip

[21]: vector_df = pd.read_csv("../data/obama_nodevectors.csv")

vector_df

[21]:
```

	node	X	Y
0	347971482	0.429952	0.032242
1	181692013	-0.391304	-0.135905
2	1433227584	0.812500	0.770574
3	394166747	0.770833	0.363461
4	20728008	-0.413043	-0.162574
...
220	549600704	0.666667	0.227302
221	21773704	0.666667	0.301933
222	14662354	0.479167	0.276551
223	14979330	-0.391304	-0.137066
224	522718572	-0.413043	-0.071466

225 rows × 3 columns

```
[22]: v1_dict = vector_df.set_index("node").to_dict()["X"]
v2_dict = vector_df.set_index("node").to_dict()["Y"]

nodes = sorted(list(set(v1_dict.keys()) | set(v2_dict.keys())))

v1_array = np.array([v1_dict[node] if node in v1_dict else 0 for node in nodes])
v2_array = np.array([v2_dict[node] if node in v2_dict else 0 for node in nodes])
```

Generalized Euclidean

Heat Diffusion

- Imagine each node as a thermometer
- Connected to other thermometers to pass heat
- If we know the heat h at time t
- What would be the heat at $t + 1$?

$$\frac{\partial h}{\partial t} = -\underset{\substack{\uparrow \\ \text{Laplacian}}}{L}h$$

Generalized Euclidean: Laplacian

- L tells us how easy it is to pass heat between nodes
- Which is via random walks
- Thus its inverse gives a sense of distance

$$\sqrt{(p-q)^T L^{-1} (p-q)}$$

Network Variance

- Not only about distances!
- Vector v : how spread out is on the network?
- Same as variance, now network variance

Network Correlation

- How are two variables related?
- Pearson works in a flat space
- What if we have a network?
- E.g. correlation between age and sharing activity in a social network

$$\rho_{x,y,G} = \frac{\text{sum}(W \times (\hat{x} \otimes \hat{y}))}{\sigma_{x,W} \sigma_{y,W}}$$

$$W = e^{-P}$$

Random Walks

- If we move randomly, we expect bump into each other
- The later we do so from what we expected, the farther we were
- Z-scores!

$$\sqrt{(p-q)^T Z^{-1} (p-q)}$$

Random Walks #2

- A^k : p of going from v_1 to v_2 in k steps (RW)
- For which k would our vectors completely overlap each other?

$$\sqrt{(p-q)^T \sum_{k=0}^{\infty} A^k (p-q)}$$

Tutorial Part #2

- Objectives:
 - Build an intuition of the measure with a simple toy experiment
 - Calculate Euclidean, variance, and correlation on a network
 - Calculate alternative Euclidean

```
nvd_session02.ipynb
[16]: import numpy as np
import pandas as pd
import networkx as nx
import network_distance as nd
import matplotlib.pyplot as plt
from scipy.stats import pearsonr
from scipy.spatial import distance

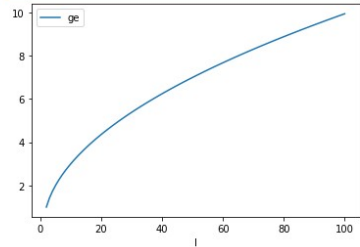

import warnings
warnings.simplefilter(action="ignore", category=FutureWarning)

•[11]: df = []
for l in range(2, 101):
    G = nx.path_graph(l) # Creating longer and longer path graphs: 0-0-0-0-0
    v1 = {0: 1}          # In the first vector, the leftmost node in the path graph has value 1, everything else has
    v2 = {l - 1: 1}      # In the second vector, the rightmost node in the path graph has value 1, everything else has
    df.append([l, nd.ge(v1, v2, G)])

df = pd.DataFrame(data = df, columns = ("l", "ge"))
df = df.set_index("l")

df.plot()
plt.show()

[20]: vector_df = pd.read_csv("../data/obama_nodevectors.csv")
```

Shortest Path Distances

NVD Seems Easy

- Just calculate shortest paths!
- But then: which ones do we choose?

Non-Optimized

- **Single** linkage
 - Always pick the shortest available
- **Complete** Linkage
 - Always pick the longest available
- **Average** Linkage
 - Pick them all and weigh the alternatives

Non-Optimized

- Single Linkage
 - $1 + 1 + 3$
- Complete Linkage
 - $3 + 2 + 2$
- Average Linkage
 - $18 / 3$

Earth Mover Distance

- Find the best set of paths
- Minimize the cost
- Similar to single linkage

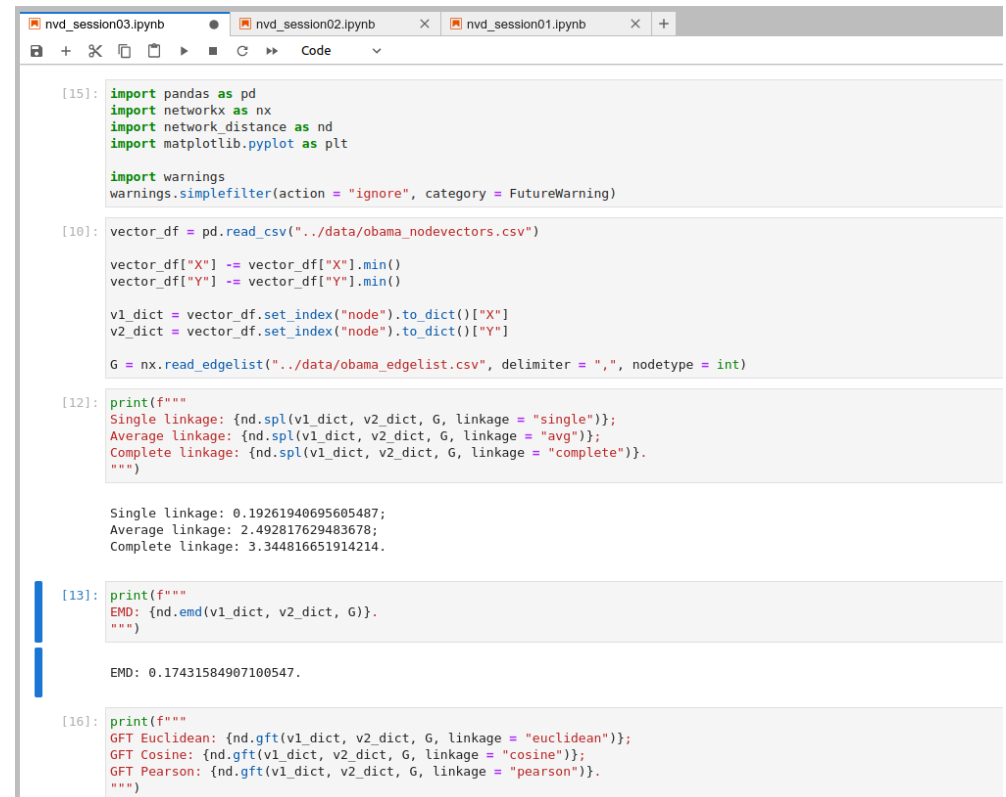

Multi Agent Path Finding

- Similar to EMD
- With constraints
- Nodes & edges have capacity limits
- E.g. cannot use the same link at the same time

Tutorial Part #3

- Objectives:
 - Experiment with different linkage criteria
 - Use optimal EMD solution
 - (Skipping ahead) Test spectral distance

```
[15]: import pandas as pd
import networkx as nx
import network_distance as nd
import matplotlib.pyplot as plt

import warnings
warnings.simplefilter(action = "ignore", category = FutureWarning)

[10]: vector_df = pd.read_csv("../data/obama_nodevectors.csv")

vector_df["X"] -= vector_df["X"].min()
vector_df["Y"] -= vector_df["Y"].min()

v1_dict = vector_df.set_index("node").to_dict()["X"]
v2_dict = vector_df.set_index("node").to_dict()["Y"]

G = nx.read_edgelist("../data/obama_edgelist.csv", delimiter = ",", nodetype = int)

[12]: print(f"""
Single linkage: {nd.spl(v1_dict, v2_dict, G, linkage = "single")};
Average linkage: {nd.spl(v1_dict, v2_dict, G, linkage = "avg")};
Complete linkage: {nd.spl(v1_dict, v2_dict, G, linkage = "complete")}.
""")

Single linkage: 0.19261940695605487;
Average linkage: 2.492817629483678;
Complete linkage: 3.344816651914214.

[13]: print(f"""
EMD: {nd.emd(v1_dict, v2_dict, G)}.
""")

EMD: 0.17431584907100547.

[16]: print(f"""
GFT Euclidean: {nd.gft(v1_dict, v2_dict, G, linkage = "euclidean")};
GFT Cosine: {nd.gft(v1_dict, v2_dict, G, linkage = "cosine")};
GFT Pearson: {nd.gft(v1_dict, v2_dict, G, linkage = "pearson")}.
""")
```

Spectral Methods

Graph Fourier Transform

- FT: decompose any signal into its component frequencies

Graph Fourier Transform

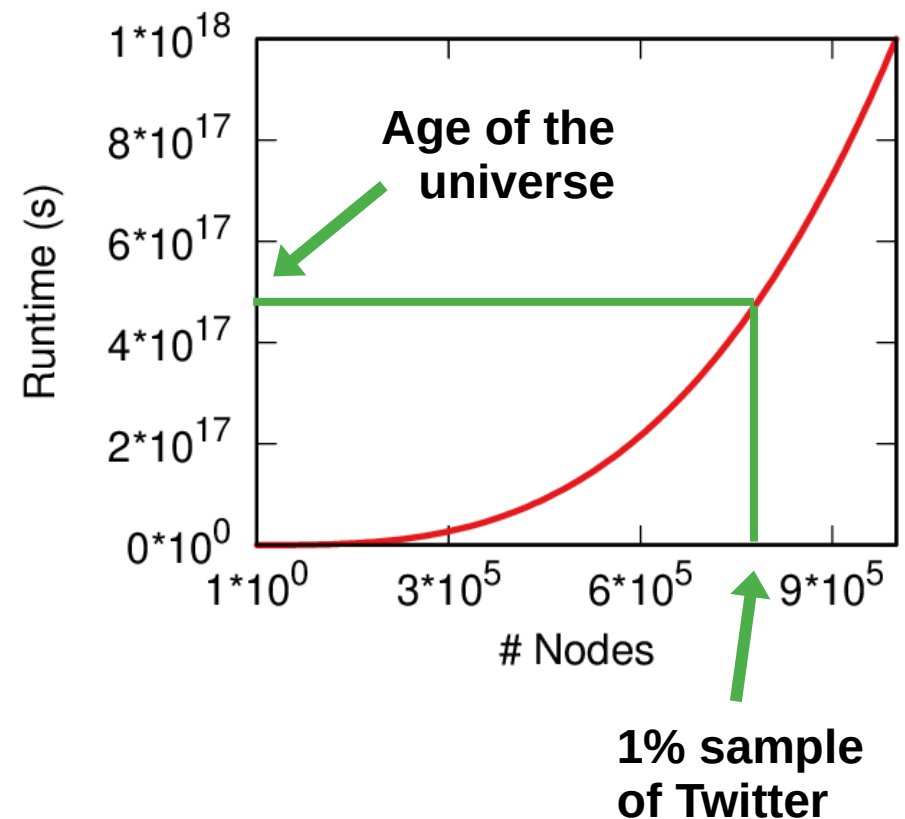

- FT: decompose any signal into its component frequencies
- GFT: same, but the components are the eigenvectors of the graph
- Remember: eigenvectors encode structure

The vector of coefficients encodes the structure and can be analyzed with classical network-agnostic measures such as Euclidean distance

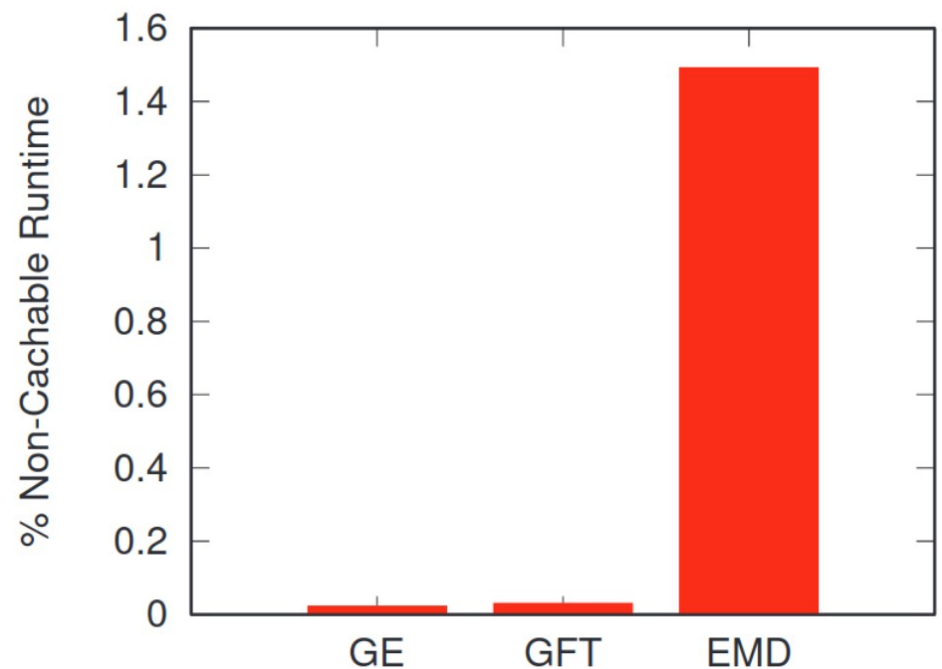

Computational Efficiency

- Expensive steps can be $O(|V|^3)$...
 - Pseudoinverse for GE
 - Shortest paths
 - Eigenvectors of Laplacian

Some Tricks

- Expensive part needs to be done once per network
- You can re-use it for all node vector pairs you have
- E.g. disease spreading on an unchanging social network

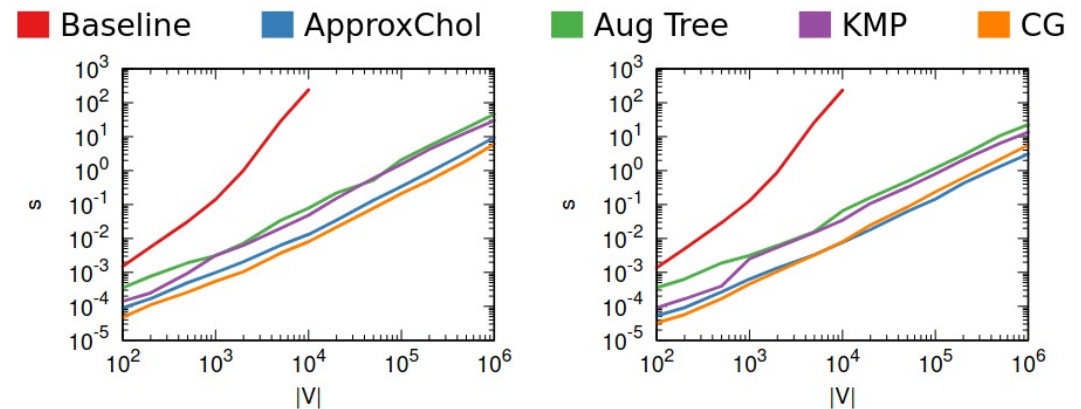

Laplacian Solvers

$$\sqrt{(p-q)^T \boxed{L^{-1}(p-q)}}$$

This part can be
calculated efficiently

Without pseudo-inverting
the Laplacian!

With Laplacian solvers (in
Julia)

(a) Erdos-Renyi

(b) Barabasi-Albert

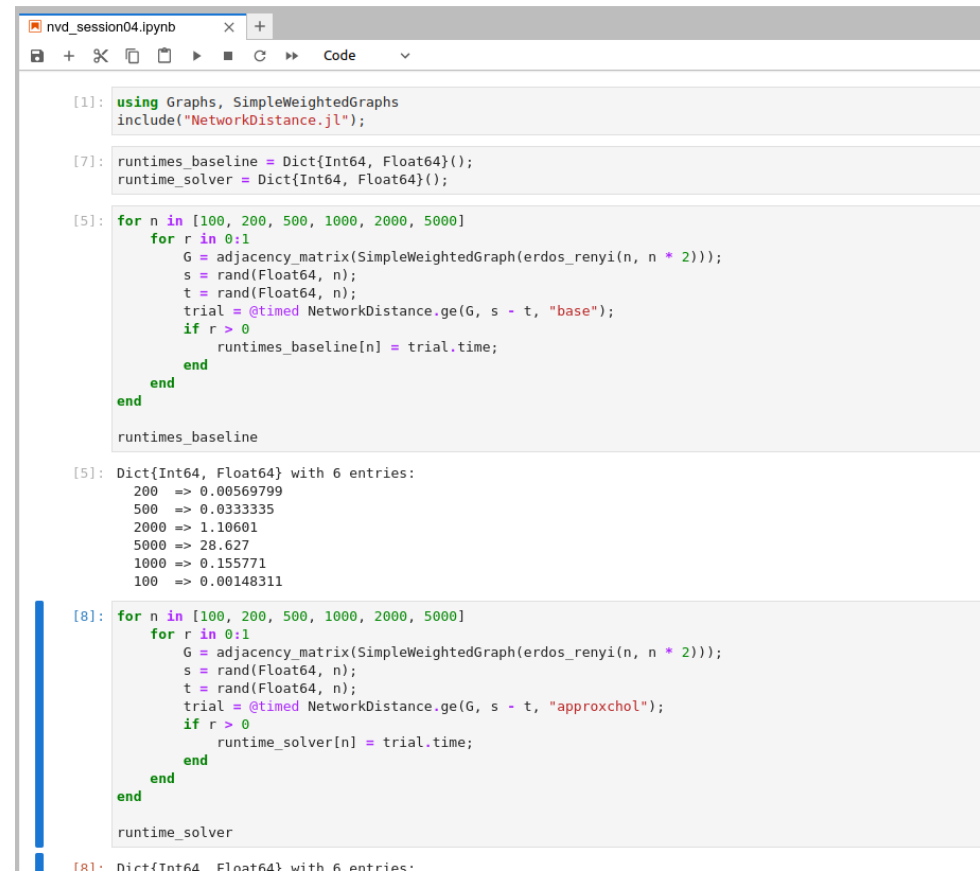

(c) Watts-Strogatz

(d) Stochastic Blockmodel

Tutorial Parts #4 & #5

- Objectives:
 - Testing runtimes
 - Experimenting with Laplacian solvers
 - Trying out some application scenarios

```
nvd_session04.ipynb
[1]: using Graphs, SimpleWeightedGraphs
    include("NetworkDistance.jl");

[7]: runtimes_baseline = Dict{Int64, Float64}{};
    runtime_solver = Dict{Int64, Float64}{};

[5]: for n in [100, 200, 500, 1000, 2000, 5000]
    for r in 0:1
        G = adjacency_matrix(SimpleWeightedGraph(erdos_renyi(n, n * 2)));
        s = rand(Float64, n);
        t = rand(Float64, n);
        trial = @timed NetworkDistance.ge(G, s - t, "base");
        if r > 0
            runtimes_baseline[n] = trial.time;
        end
    end
end
runtimes_baseline

[5]: Dict{Int64, Float64} with 6 entries:
  200 => 0.00569799
  500 => 0.0333335
  2000 => 1.10601
  5000 => 28.627
  1000 => 0.155771
  100 => 0.00148311

[8]: for n in [100, 200, 500, 1000, 2000, 5000]
    for r in 0:1
        G = adjacency_matrix(SimpleWeightedGraph(erdos_renyi(n, n * 2)));
        s = rand(Float64, n);
        t = rand(Float64, n);
        trial = @timed NetworkDistance.ge(G, s - t, "approxchol");
        if r > 0
            runtime_solver[n] = trial.time;
        end
    end
end
runtime_solver
